Anthony GENEVOIS

Groups acting on quasi-median graphs. An introduction
<http://tsg.centre-mersenne.org/item?id=TSG_2017-2019__35__43_0>
GROUPS ACTING ON QUASI-MEDIAN GRAPHS. AN INTRODUCTION

Anthony Genevois

Abstract. — Quasi-median graphs have been introduced by Mulder in 1980 as a generalisation of median graphs, known in geometric group theory to naturally coincide with the class of CAT(0) cube complexes. In his PhD thesis, the author showed that quasi-median graphs may be useful to study groups as well. In the present paper, we propose a gentle introduction to the theory of groups acting on quasi-median graphs.

1. Introduction

CAT(0) cube complexes were introduced by Gromov in his seminal paper [17] as a convenient source of examples of CAT(0) and CAT(-1) groups. But their strength really appeared with the recognition of the central role played by the combinatorics of their hyperplanes, initiated by Sageev in his thesis [26]. Since then, several still open conjectures for CAT(0) spaces were verified for CAT(0) cube complexes, including the (bi)automaticity of cubulated groups [24], the Tits Alternative for groups acting freely on finite-dimensional CAT(0) cube complexes [27], and the Rank Rigidity Conjecture [6]. Recently, CAT(0) cube complexes were also crucial in the proof of the famous virtual Haken conjecture [1].

Independently, Roller [25] and Chepoï [8] realised that the class of CAT(0) cube complexes can be naturally identified with the class of the so-called median graphs. These graphs were known by graph theorists for a long time since they were introduced by Nebeský in 1971 [23]. Since then, several classes of graphs were introduced as generalisations of median graphs (see for instance [7] and references therein), including the main subject of this article, quasi-median graphs, which were introduced by Mulder in 1980 [22] and more extensively studied by Bandelt, Mulder and Wilkeit in 1994 [3].
In [11], we showed that quasi-median graphs appear naturally in several places in geometric group theory, and that finding group actions on such graphs may be extremely useful. The goal of this article is to give a gentle introduction to the formalism introduced in [11].

The paper is organised as follows. In Section 2, we notice that the geometry of quasi-median graphs is quite similar to the geometry of CAT(0) cube complexes. In particular, we generalise the definition of hyperplanes and show that geometry essentially reduces to the combinatorics of the hyperplanes. In Section 3, examples of groups acting on quasi-median graphs are given. We focus on graph products, wreath products, and diagram groups. In Section 4, we introduce and study rotative stabilisers of hyperplanes. They are used to embed graph products into groups acting on quasi-median graphs, and, under some assumptions, a decomposition as a semidirect product is proved. Finally, Sections 5 and 6 are dedicated to topical-transitive actions, which can be used to prove combination theorems. Applications to the groups mentioned in Section 3 are given. We conclude this article by describing in Section 7 recent successes in the geometric study of automorphism groups of graph products based on quasi-median graphs.

2. Quasi-median graphs look like CAT(0) cube complexes

Quasi-median graphs may be defined in many different ways; see for instance [3]. In [11], the definition we used is the following:

**Definition 2.1.** — A graph is weakly modular if it satisfies the following two conditions:

- (triangle condition) for any vertex $u$ and any two adjacent vertices $v, w$ at distance $k$ from $u$, there exists a common neighbor $x$ of $v, w$ at distance $k - 1$ from $u$;
- (quadrangle condition) for any vertices $u, z$ at distance $k$ apart and any two neighbors $v, w$ of $z$ at distance $k - 1$ from $u$, there exists a common neighbor $x$ of $v, w$ at distance $k - 2$ from $u$.

A graph is quasi-median if it is connected, weakly modular and if it does not contain $K_{4}^{-}$ and $K_{3,2}$ as induced subgraphs. See Figures 2.1 and 2.2.

Although this definition turns out to be convenient to work with, the analogy with CAT(0) cube complexes is not clear. This analogy becomes more explicit thanks to the following two statements (which were originally proved only for finite graphs). We refer to the corresponding references for the needed definitions.
Figure 2.1. The triangle and square conditions.

Figure 2.2. The graphs $K_4^-$ and $K_{3,2}$.

Theorem 2.2. — [2] Let $X$ be a finite graph. The following statements are equivalent:

- $X$ is median;
- $X$ is a retract of a hypercube;
- $X$ is obtained from cubes by gated amalgams.

Theorem 2.3. — [28, 3] Let $X$ be a finite graph. The following statements are equivalent:

- $X$ is quasi-median;
- $X$ is a retract of a product of complete graphs;
- $X$ is obtained from prisms (i.e., products of complete graphs) by gated amalgams.

Roughly speaking, if one says that CAT(0) cube complexes or median graphs are obtained by gluing cubes together in a “nonpositively-curved way”, then quasi-median graphs are obtained by gluing prisms together in a “nonpositively-curved way”. So edges become cliques, and cubes become prisms. This analogy motivates the following definition, which mimics the definition of hyperplanes in CAT(0) cube complexes. See Figure 2.3 for examples.
Figure 2.3. A quasi-median graph and some of its hyperplanes.

**Definition 2.4.** A hyperplane is an equivalence class of edges, where two edges $e$ and $e'$ are said equivalent whenever there exists a sequence of edges $e_0 = e, e_1, \ldots, e_{n-1}, e_n = e'$ such that, for every $1 \leq i \leq n-1$, either $e_i$ and $e_{i+1}$ are opposite sides of some square or they are two sides of some triangle. Alternatively, if we say that two cliques are parallel whenever they respectively contain two opposite sides of some square, then a hyperplane is the collection of edges of some class cliques with respect to the transitive closure of parallelism.

One says that an edge or a clique is dual to a given hyperplane if it belongs to the associated class of edges. Of course, because two distinct equivalence classes are necessarily disjoint, an edge or a clique is dual to a unique hyperplane.

**Definition 2.5.** The carrier of hyperplane $J$, denoted by $N(J)$, is the subgraph generated by the union of all the edges of $J$. A fiber of $J$ is a connected component of $\partial J = N(J) \setminus J$, i.e., the subgraph obtained from $N(J)$ by removing the interiors of the edges of $J$.

Now, the point is that, in the same way that the geometry of a CAT(0) cube complex reduces to the combinatorics of its hyperplanes, the geometry of a quasi-median graph reduces as well to the combinatorics of its hyperplanes. More precisely:

**Theorem 2.6 ([11, Proposition 2.15 and 2.30]).** Let $X$ be a quasi-median graph. For every hyperplane $J$, the following statements hold.

- The subgraph $X \setminus J$ obtained from $X$ by removing the interiors of the edges of $J$ is disconnected, possibly with infinitely many connected components. Each such component, called a sector, is gated.
A fiber of $J$ is a gated subgraph; in particular, it is a quasi-median graph on its own right.

The carrier of $J$ is naturally isometric to a product $F \times C$ where $F$ is an arbitrary fiber of $F$ and $C$ an arbitrary clique dual to $J$. Furthermore, $N(J)$ is a gated subgraph.

Moreover, a path in $X$ is a geodesic if and only if it crosses at most once each hyperplane. As a consequence, the distance between any two vertices of $X$ coincides with the number of hyperplanes which separate them.

Recall that, given a graph $X$ and a subgraph $Y \subset X$, a gate in $Y$ for some vertex $x \in X$ is a vertex $y \in Y$ such that, for every $z \in Y$, there exists a geodesic between $x$ and $z$ passing through $y$. If every vertex of $X$ has a gate in $Y$, then $Y$ is gated. It is worth noticing that a gated subgraph must be convex. In fact, gated subgraphs in quasi-median graphs play the same role as convex subcomplexes in CAT(0) cube complexes. The reason is that one can project vertices onto gated subgraphs, just by taking the corresponding gates: note that the gate, when it exists, is the unique vertex of the subgraph minimising the distance to the initial vertex. In median graphs, convex subgraphs are always gated, but it is no longer true in quasi-median graphs: an edge in a triangle is obviously convex, but the vertex of our triangle which does not belong to this edge have two nearest-point projections. For more information on projections onto gated subgraphs in quasi-median graphs, we refer to [11, Section 2.3].

Let us mention that, in the same way that median graphs can be filled in to get a CAT(0) space, quasi-median complexes, ie., prism complexes obtained from quasi-median graphs by filling in every clique with a simplex and every one-skeleton of an $n$-cube with an $n$-cube, define CAT(0) spaces as well.

**Theorem 2.7** ([11, Theorem 2.120]). — Quasi-median complexes are CAT(0).

It is worth noticing that a CAT(0) cube complex can be naturally associated to any quasi-median graph. Indeed, endow a given quasi-median graph $X$ with a structure of wallspace by declaring that a sector and its complement is wall, and next cubulate this wallspace to get a CAT(0) cube complex $C(X)$. See Figure 2.4 for an example. Then the canonical map $X \to C(X)$ is a quasi-isometry, which is furthermore equivariant, meaning that if a group acts on $X$ then it naturally acts on $C(X)$ as well. As a consequence, every group acting geometrically (resp. properly, fixed-point
freely) on a quasi-median graph acts geometrically (resp. properly, fixed-point freely) on a CAT(0) cube complex.

Therefore, a natural question is: why do we care about quasi-median graphs? The first reason is that a quasi-median graph may appear more naturally than a CAT(0) cube complex, making the quasi-median graph easier to handle. For instance, we are convinced that quasi-median graphs provide the good framework to study the geometry of graph products (see Section 3). The second reason is that one can exploit the specific structure of hyperplanes in quasi-median graphs to define particular kinds of actions on such graphs which provide interesting information on the group (see Sections 4, 5 and 6).

3. Quasi-median graphs appear in Nature

In this section, our goal is to describe four classes of groups which act naturally on quasi-median graphs: graph products, (some) wreath products, diagram products and some graphs of groups.
3.1. Graph products

Let us begin by recalling the definition of graph products, as introduced in [16]:

**Definition 3.1.** — Let $\Gamma$ be a simplicial graph and $\mathcal{G}$ a collection of groups indexed by the vertices of $\Gamma$. The graph product $\Gamma \mathcal{G}$ is the group defined by the relative presentation

$$\langle G_u, u \in V(\Gamma) \mid [G_u, G_v] = 1, (u, v) \in E(\Gamma) \rangle,$$

where $[G_u, G_v] = 1$ is an abbreviation for: $[g, h] = 1$ for every $g \in G_u$ and $h \in G_v$.

Notice that, if $\Gamma$ has no edges, then $\Gamma \mathcal{G}$ coincides with the free product of all the groups of $\mathcal{G}$; and if $\Gamma$ is complete graph, then $\Gamma \mathcal{G}$ coincides with the direct sum of all the groups of $\mathcal{G}$. Usually, one says that graph products interpolate between free products and direct sums. Next, notice also that, if all the groups of $\mathcal{G}$ are infinite cyclic, we recover right-angled Artin groups; and if all the groups of $\mathcal{G}$ are cyclic of order two, we recover the right-angled Coxeter groups.

**Theorem 3.2.** — [11, Proposition 8.2] Let $\Gamma$ be a simplicial graph and $\mathcal{G}$ a collection of groups indexed by $V(\Gamma)$. The Cayley graph $X(\Gamma, \mathcal{G})$ of $\Gamma \mathcal{G}$ associated to the generating set $\bigsqcup_{G \in \mathcal{G}} \{1\}$ is a quasi-median graph.

Graph products are our examples where the link between groups and graphs is the strongest. In [11], one of our major contributions to the study of geometric properties of graph products is the characterisation of relatively hyperbolic graph products. Before stating our theorem, we need to introduce some vocabulary.

Given a finite simplicial graph $\Gamma$ and a collection of groups $\mathcal{G}$ indexed by $V(\Gamma)$, we will say that a subgraph $\Lambda \subseteq \Gamma$ is vast if the subgroup of $\Gamma \mathcal{G}$ generated by the vertex-groups corresponding to the vertices of $\Lambda$, i.e., $\Lambda \mathcal{G}$, is infinite; otherwise, $\Lambda$ is said narrow. Notice that a subgraph is narrow if and only if it is complete and all the vertex-groups labelling its vertices are finite. A join $\Lambda_1 \ast \Lambda_2 \subseteq \Gamma$ is large if both $\Lambda_1$ and $\Lambda_2$ are vast.

**Definition 3.3.** — Let $\Gamma$ be a finite simplicial graph and $\mathcal{G}$ a collection of groups labelled by $V(\Gamma)$. For every subgraph $\Lambda \subset \Gamma$, let $\text{cp}(\Lambda)$ denote the subgraph of $\Gamma$ generated by $\Lambda$ and the vertices $v \in \Gamma$ such that $\text{link}(v) \cap \Lambda$ is vast. Now, define the collection of subgraphs $\mathcal{J}^n(\Gamma)$ of $\Gamma$ by induction in the following way:
• $\mathcal{J}^0(\Gamma)$ is the collection of all the large joins in $\Gamma$;
• if $C_1$, $\ldots$, $C_k$ denote the connected components of the graph whose set of vertices is $\mathcal{J}^n(\Gamma)$ and whose edges link two subgraphs with vast intersection, we set

$$
\mathcal{J}^{n+1}(\Gamma) = \left( \bigcup_{\Lambda \in C_1} \Lambda, \ldots, \bigcup_{\Lambda \in C_k} \Lambda \right).
$$

Because $\Gamma$ is finite, the sequence $(\mathcal{J}^n(\Gamma))$ must eventually be constant and equal to some collection $\mathcal{J}^\infty(\Gamma)$. Finally, let $\mathcal{J}(\Gamma)$ denote the collection of subgraphs of $\Gamma$ obtained from $\mathcal{J}^\infty(\Gamma)$ by adding the singletons corresponding to the vertices of $\Gamma \setminus \bigcup \mathcal{J}^\infty(\Gamma)$.

**Theorem 3.4.** — [11, Theorem 8.35] Let $\Gamma$ be a finite simplicial graph not reduced to a single vertex and $G$ a collection of finitely generated groups labelled by $V(\Gamma)$. The graph product $\Gamma G$ is relatively hyperbolic if and only if $\mathcal{J}(\Gamma) \neq \{\Gamma\}$. If so, $\Gamma G$ is hyperbolic relatively to $\{\Lambda G \mid \Lambda \in \mathcal{J}(\Gamma)\}$.

**Example 3.5.** — Let $\Gamma G$ denote the graph product illustrated by Figure 3.1. Then $\Gamma G$ is hyperbolic relatively to the three subgroups respectively generated by the vertex-groups of the three red subgraphs.

![Figure 3.1. A relatively hyperbolic graph product and its peripheral subgroups.](image)

**3.2. Wreath products**

Recall that, given two groups $G$ and $H$, the wreath product $G \wr H$ is the semidirect product

$$
\left( \bigoplus_{h \in H} G \right) \rtimes H
$$

SÉMINAIRE DE THÉORIE SPECTRALE ET GÉOMÉTRIE (GRENOBLE)
where $H$ acts on the direct sum by permuting the coordinates. Often, such groups are described as lamplighter groups in the following way. Fix two generating sets $R$ and $S$ of $G$ and $H$ respectively. Notice that $R \cup S$, when we identify $G$ with its copy in the direct sum labelled by the identity element, generates $G \wr H$. An element $((g_h), h \in H, k)$ of the wreath product is thought of as the following configuration: each vertex $h \in H$ of the Cayley graph of $H$ (corresponding to $S$) is a lamp whose color is $g_h \in G$, and an arrow points to the vertex $k \in H$ to indicate the position of the lamplighter. Now, right-multiplying this element by some $r \in R$ corresponds to modifying the color of the lamp at the vertex $k \in H$, i.e., where the lamplighter is, from $g_k$ to $g_k r$; and right-multiplying the element by some $s \in S$ corresponds to moving the lamplighter from $k$ to the adjacent vertex $ks$. Thus, the Cayley graph of $G \wr H$ (corresponding the generating set $R \cup S$) encodes a lamplighter moving along the Cayley graph of $H$ and modifying the colors of the lamps along its path.

Now, suppose that the group $H$ acts on a CAT(0) cube complex $X$, and suppose without loss of generality that $X$ contains a vertex $x_0 \in X$ with trivial stabiliser. In the previous description, we will replace the Cayley graph of $H$ (i.e., the graph on which the lamplighter moves) with the cube complex $X$; the lamps will be the vertices of the orbit $\Omega = H \cdot x_0 \subset X$; and the lamplighter (i.e., the arrow) will be replaced with a non empty finite convex subcomplex of $X$. Formally, the situation is the following:

**Definition 3.6.** — A wreath $(C, \varphi)$ is the data of a non empty finite convex subcomplex $C \subset X$ and a function $\varphi : \Omega \to G$ with finite support, i.e., $\varphi(p) = 1$ for all but finitely many $p \in \Omega$. The graph of wreaths $\mathfrak{W}$ is the graph whose vertices are the wreaths and whose edges link two wreaths $(C, \varphi)$ and $(Q, \psi)$ either if $\varphi = \psi$ and if there exists a unique hyperplane intersecting exactly one of $C$ and $Q$; or if $C = Q$ and if $\varphi$ and $\psi$ differ on a single point of $C \cap \Omega = Q \cap \Omega$.

When $H$ has a Cayley graph which is a median graph, or equivalently when $H$ admits an action on a CAT(0) cube complex which is free and transitive on the vertices, then we may identify the group $H$, the orbit $\Omega$ and the cube complex $X$. This happens for instance when $H$ is a free abelian group or a non-abelian free group. A piece of the graph of wreaths associated to $\mathbb{Z}_3 \wr \mathbb{Z}$ is illustrated by Figure 3.2.

A funny interpretation is the following. By replacing the arrow by a subcomplex, the lamplighter becomes “quantum”. It has no precise position, it is everywhere inside the subcomplex, which can be thought of as a “cloud”, and it can modify the color of any lamp inside this cloud (but just one at
each time). The cloud moves by adding or removing a hyperplane from the corresponding subcomplex, the operation being allowed only if the resulting subcomplex remains convex and non empty.

**Theorem 3.7.** — [11, Proposition 9.10] The graph of wreaths $\mathcal{W}$ is quasi-median.

(We used the same idea in [13] to construct actions of wreath products on median spaces, reproving that acting properly on a CAT(0) cube complex and being a-T-menable are stable under wreath products.)

### 3.3. Diagram products

In [19], Guba and Sapir introduced diagram products from the class of diagram groups [18], in a similar way that graph products can be derived from right-angled Artin groups.

**Definition 3.8.** — Let $\mathcal{P} = \langle \Sigma \mid \mathcal{R} \rangle$ be a semigroup presentation. We suppose that, for every relation $u = v \in \mathcal{R}$, the relation $v = u$ does not belong to $\mathcal{R}$; as a consequence, $\mathcal{R}$ does not contain relations of the form $u = u$. Let $S(\mathcal{P})$ denote the square complex

- whose vertices are the words written over the alphabet $\Sigma$;
- whose edges have the form $(a, u \to v, b)$ for some relation $u = v \in \mathcal{R}$, linking the vertices $aub$ and $avb$;
- whose squares have the form $(a, u \to v, b, p \to q, c)$ for some relations $u = v, p = q \in \mathcal{R}$, linking the vertices $aubpc, avbpc, aubqc$ and $avbqc$. 

Figure 3.2. A piece of the graph of wreaths associated to $\mathbb{Z}_3 \wr \mathbb{Z}$. 

SÉMINAIRE DE THÉORIE SPECTRALE ET GÉOMÉTRIE (GRENOBLE)
Now, fix a collection of groups $\mathcal{G}$ indexed by the alphabet $\Sigma$, and let $S(\mathcal{P}, \mathcal{G})$ be the complex of groups (we refer to [4, Chapter II.12] for more information on (simple) complexes of groups) such that

- the underlying complex is $S(\mathcal{P})$;
- the vertex-group associated to the word $s = s_1 \cdots s_n$ is $G_s = G_{s_1} \times \cdots \times G_{s_n}$;
- the edge-group associated to the edge $(a, u \to v, b)$ is $G_a \times G_b$;
- the square-groups are all trivial;
- the embedding of an edge-group into a vertex-group coincides the canonical embedding of a factor into a direct product.

Fixing some baseword $w \in \Sigma^+$, the diagram product $D(\mathcal{P}, \mathcal{G}, w)$ is the fundamental group of the complex of groups $S(\mathcal{P}, \mathcal{G}, w)$ corresponding to the connected component of $S(\mathcal{P}, \mathcal{G})$ containing the vertex $w$.

When all the groups of $\mathcal{G}$ are trivial, one recovers the definition of diagram groups as fundamental groups of Squier complexes [18].

**Example 3.9.** — Let us mention a few concrete examples of diagram products. We refer to [11, Section 10.6] for more details.

- If $\mathcal{P} = \langle a, b, p \mid a = ap, b = pb \rangle$ and $\mathcal{G} = \{G_a = G_b = \{1\}, G_p = G\}$ for some group $G$, then the diagram product $D(\mathcal{P}, \mathcal{G}, ab)$ is isomorphic to the wreath product $G \wr \mathbb{Z}$.
- If $\mathcal{P} = \langle a, b, p \mid a = ap, b = pb \rangle$ and $\mathcal{G} = \{G_a = G, G_b = H, G_p = \{1\}\}$ for some groups $G$ and $H$, then the diagram product $D(\mathcal{P}, \mathcal{G}, ab)$ admits
  $$G \bullet H = \langle G, H, t \mid [g, t^n h t^{-n}] = 1, g \in G, h \in H, n \geq 0 \rangle$$
  as a (relative) presentation. Interestingly, $\mathbb{Z} \bullet \mathbb{Z}$ is a finitely generated but not finitely presented group which is isomorphic to the subgroup $\langle a, c, bd \rangle$ in the direct product of two free groups $\langle a, b \rangle \times \langle c, d \rangle$.
- Consider the semigroup presentation
  $$\mathcal{P} = \langle a, b, c, d \mid ab = ac, bd = cd \rangle$$
  and the collection $\mathcal{G} = \{G_b = G_c = \{1\}, G_a = G, G_d = H\}$ for some groups $G, H$. Then the diagram product $D(\mathcal{P}, \mathcal{G}, abd)$ admits
  $$G \Box H = \langle G, H, t \mid [g, h] = [g, h^t] = 1, g \in G, h \in H \rangle$$
  as a (relative) presentation.
Thanks to the alternative description of diagram groups given in [11, Section 10], we generalised the definition in [12] by looking at *symmetric diagram groups* [18, 10]. It would be too long to define this generalisation here, but the point is that there exist a *symmetric diagram product* $D_s(P, G, w)$ and an *annular diagram product* $D_a(P, G, w)$, such that

$$D(P, G, w) \subset D_a(P, G, w) \subset D_s(P, G, w).$$

To avoid ambiguity, the diagram product $D(P, G, w)$ will be sometimes referred to as the *planar diagram product*. Each of these products acts on quasi-median graphs, denoted by $X(P, G, w)$, $X_a(P, G, w)$ and $X_s(P, G, w)$ respectively [11, 12]. For instance, the graph $X(P, G, w)$, roughly speaking, coincides with a connected component of the natural Cayley graph of the fundamental groupoid corresponding to the complex of groups $S(P, G, w)$.

### 3.4. Right-angled graphs of groups

In [11], we also studied *right-angled graphs of groups*, which are roughly speaking specific gluings of graph products. It would be too long to define the class of right-angled graphs of groups acting topically-transitively on quasi-median graphs which we studied in [11], so we refer to [11, Section 11] for more details, and we focus on a specific subclass, namely *Cartesian graphs of groups*. A *Cartesian graphs of groups* is a graph of groups such that groups are direct products, edges are factors of vertices, and monomorphisms are canonical embeddings. We refer to [11, Section 11] for more details on the quasi-median geometry of these groups.

**Example 3.10.** — Let us mention a few concrete examples of fundamental groups of Cartesian graphs of groups. We refer to [11, Section 11.4] for more details.

- Let $A$ be a group and $B_1, B_2$ two copies of a group $B$. Consider the HNN extension $(A \times (B_1 * B_2) * B)$ associated to the monomorphisms $B \to B_1$ and $B \to B_2$. We recover the product $A \Box B$ from Example 3.9, which admits

$$\langle A, B, t | [a, b] = [a, b^t] = 1, a \in A, b \in B \rangle$$

as a (relative) presentation.

- Let $A_1, A_2$ be two copies of a group $A$. Consider the HNN extension $(A_1 \times A_2) * A$ associated to the monomorphisms $A \to A_1$ and $A \to$
A$_2$. This is a Cartesian graph of groups, and its fundamental group, which we denote by $A^{\ast}$, admits

$$\langle A, t \mid [a, a^t] = 1, a \in A \rangle$$

as a (relative) presentation. Notice that, if $A$ is infinite cyclic, we recover the group introduced in [5], which was the first example of fundamental group of a 3-manifold which is not subgroup separable.

- Let $A$ be a group and $B_1, B_2$ two copies of a group $B$. Consider the HNN extension $(B_1 \times A \times B_2) \ast_B$ associated to the monomorphisms $B \to B_1$ and $B \to B_2$. The group we obtain, which we denote by $A \rtimes B$, admits

$$\langle A, B, t \mid [a, b^t] = [b, b^t] = 1, a \in A, b \in B \rangle$$

as a (relative) presentation.

4. Rotative actions on quasi-median graphs

The main difference between CAT(0) cube complexes and quasi-median graphs is that hyperplanes may separate the graph into more than two pieces. In fact, in the cases which interest us, the number of sectors delimited by a given hyperplane turns out to be infinite. Therefore, an isometry of infinite order stabilising a fixed hyperplane may only “rotate” this hyperplane without “translating” vertices. More formally:

**Definition 4.1.** — Let $G$ be a group acting on a quasi-median graph $X$ and $J$ a hyperplane of $X$. The rotative stabiliser of $J$ is

$$\text{stab}_\bigtriangleup(J) = \bigcap \{ \text{stab}(C) \mid C \text{ clique of } J \}.$$  

An interesting remark is that the rotative stabilisers of two transverse hyperplanes commute, i.e., any element of one stabiliser commutes with any element of the other. Loosely speaking, the situation is similar to two rotations in the space whose axes are orthogonal. On the other hand, it is not difficult to show that the group of isometries generated by the rotative stabilisers of two non transverse hyperplanes decomposes as the free product of these two rotative stabilisers (provided that vertex-stabilisers are trivial). Essentially, it is sufficient to play ping-pong with the sectors delimited by the hyperplanes. Generalising the argument to an arbitrary collection of hyperplanes leads to the following statement:
Theorem 4.2. — [11, Theorem 8.43] Let $G$ be a group acting on a quasi-median graph $X$ with trivial vertex-stabilisers. For every hyperplane $J$, choose a residually finite subgroup $H_J$ of its rotative stabiliser. If $\Gamma$ is an induced finite subgraph of the crossing graph of $X$, there exists a collection $\mathcal{G}$ of finite-index subgroups of our $H_J$’s such that the graph product $\Gamma \mathcal{G}$ embeds into $G$.

In a quasi-median graph $X$, the crossing graph of $X$ is the graph, denoted by $\Delta X$, whose vertices are the hyperplanes of $X$ and whose edges link two transverse hyperplanes. An interesting particular case of the previous statement is when the $H_J$’s are all infinite cyclic.

Corollary 4.3. — Let $G$ be a group acting on a quasi-median graph $X$ with trivial vertex-stabilisers and with infinite non torsion rotative stabilisers. If $\Gamma$ is a finite induced subgraph in the crossing graph of $X$, then the right-angled Artin group $A(\Gamma)$ embeds into $G$.

In general, describing the crossing graph of a quasi-median graph is difficult, but for graph products, one gets the following nice description. Let $\Gamma$ be a simplicial graph and $\mathcal{G}$ a collection of non trivial groups indexed by $V(\Gamma)$. The crossing graph of the quasi-median graph $X(\Gamma, \mathcal{G})$ coincides with the graph

- whose vertices are the conjugates of vertex-groups $gG_u g^{-1}$;
- whose edges link two conjugates $gG_u g^{-1}$ and $hG_v h^{-1}$ if they commute, i.e., any element of one conjugate commutes with any element of the other.

Therefore, the crossing graph $\Delta X(\Gamma, \mathcal{G})$ naturally generalises the extension graph defined for right-angled Artin groups in [21], and Theorem 4.2 generalises [21, Theorem 2].

Pushing further the argument used to prove Theorem 4.2, it is possible to find a structure theorem for groups acting on quasi-median graphs with “sufficiently large” rotative stabilisers.

Definition 4.4. — Let $G$ be a group acting on a quasi-median graph $X$ and $\mathcal{J}$ a collection of hyperplanes. The action $G \acts X$ is $\mathcal{J}$-rotative if, for every $J \in \mathcal{J}$, the rotative stabiliser $\text{stab}_\mathcal{J}(J)$ acts transitively and freely on the set of sectors delimited by $J$.

Before stating our theorem, we also need the following definition: given a quasi-median graph $X$, a collection of hyperplanes $\mathcal{J}$ and a base vertex $x_0 \in X$, one says that a subcollection $\mathcal{J}_0 \subset \mathcal{J}$ is $x_0$-peripheral if, for every $J \in \mathcal{J}_0$, there does not exist a hyperplane of $\mathcal{J}$ separating $J$ and $x_0$. 

SÉMINAIRE DE THÉORIE SPECTRALE ET GÉOMÉTRIE (GRENOBLE)
Theorem 4.5. — [11, Theorem 10.54] Let $G$ be a group acting $\mathcal{J}$-rotatively on a quasi-median graph $X$. Fix a basepoint $x_0 \in X$. If $Y \subset X$ denotes the intersection of the sectors containing $x_0$ which are delimited by a hyperplane of $\mathcal{J}$, then

$$G = \text{Rot}({\mathcal{J}}) \rtimes \text{stab}(Y), \text{ where } \text{Rot}(\mathcal{J}) = \langle \text{stab}_\mathcal{G}(J), J \in \mathcal{J} \rangle.$$ 

Moreover, if $\mathcal{J}_0 \subset \mathcal{J}$ denotes the unique maximal $x_0$-peripheral subcollection of $\mathcal{J}$, then $\text{Rot}(\mathcal{J})$ decomposes as a graph product $\Delta \mathcal{G}$, where $\Delta$ is the graph whose vertices are the hyperplanes of $\mathcal{J}_0$ and whose edges link two hyperplanes which are transverse, and where $\mathcal{G} = \{ \text{stab}_\mathcal{G}(J) \mid J \in \mathcal{J}_0 \}$.

As an application, we showed in [11, Theorem 10.58] that (planar) diagram products decompose as semidirect products between a graph product and their underlying diagram groups. By taking collections of infinite cyclic groups and trivial diagram groups, it implies that many right-angled Artin groups turn out to be diagram groups as well [11, Corollary 10.60]. In [12], we generalised this argument and proved the following statement (see also [20, Theorem 5.7] for planar diagram groups):

Theorem 4.6. — Let $D$ be a planar (resp. annular, braided) diagram group. There exist a subgroup $R$ of some right-angled Artin group and a subgroup $S$ of Thompson’s group $F$ (resp. $T$, $V$), such that $D$ decomposes as the short exact sequence

$$1 \to R \to D \to S \to 1.$$ 

As a consequence, any simple diagram group embeds into the corresponding Thompson’s group. Our motivation in [12] was to construct new subgroups of Thompson’s group $V$. For instance, we were able to prove that Higman’s groups $V_{n,r}$, Houghton’s groups $H_n$ and groups of quasi-automorphisms $QV_{n,r}$ embed into $V$.

5. Topical-transitive actions on quasi-median graphs I

An interesting point is that, in most of the examples of groups acting on quasi-median graphs that we know, combination theorems can be proved with respect to clique-stabilisers. Let us illustrate such arguments with the following statement.

Theorem 5.1. — Let $\Gamma$ be a finite simplicial graph and $\mathcal{G}$ a collection of groups indexed by the vertices of $\Gamma$. Suppose that every group of $\mathcal{G}$ acts metrically properly on a $\text{CAT}(0)$ cube complex. Then so does the graph product $\Gamma \mathcal{G}$.
Sketch of proof. For every $G \in \mathcal{G}$, fix a CAT(0) cube complex $X(G)$ on which it acts metrically properly; via the orbit map

$$\mathcal{O} : \begin{cases} G & \to X(G) \\ g & \mapsto g \cdot x_0(G) \end{cases},$$

where $x_0(G) \in X(G)$ is a fixed vertex, one may naturally endow $G$ with a structure of wallspace, i.e., set

$$\mathcal{W}(G) = \left\{ \{ \mathcal{O}^{-1}(D), \mathcal{O}^{-1}(D^c) \} \mid D \text{ halfspace of } X \right\}.$$

Now, fix a clique $C$ of the quasi-median graph $X(\Gamma, \mathcal{G})$ on which $\Gamma \mathcal{G}$ acts. Recall that $X(\Gamma, \mathcal{G})$ is the Cayley graph of $\Gamma \mathcal{G}$ with respect to the generating set $\bigcup_{G \in \mathcal{G}} \{ 1 \}$. As a consequence, the cliques of $X(\Gamma, \mathcal{G})$ coincide with cosets of vertex-groups. Therefore, there exist some $g \in \Gamma \mathcal{G}$ and some $G \in \mathcal{G}$ such that $C = gG$. The walls defined on $G$ naturally define walls on the clique $C$ (notice that this transfer does not depend on our choice of $g$, which is used to identify $C$ with $G$, since $g$ is uniquely determined up to right-multiplying by an element of $G$ and that $\mathcal{W}(G)$ is $G$-invariant), and we may extend them as walls on the whole quasi-median graph by setting

$$\overline{\mathcal{W}}(C) = \left\{ \{ \text{proj}_{C}^{-1}(D), \text{proj}_{C}^{-1}(D^c) \} \mid D, D^c \in \mathcal{W}(C) \right\},$$

where $\mathcal{W}(C)$ denotes the collection of walls on $C$ induced by the walls of $G$. Thus, one gets a collection of walls

$$\bigcup_{C \text{ clique}} \overline{\mathcal{W}}(C)$$

on $X(\Gamma, \mathcal{G})$, which is $\Gamma \mathcal{G}$-invariant by construction. However, in general infinitely many walls separate two given vertices of our graph. Nevertheless, it turns out that, if one removes duplicated walls (i.e., walls inducing the same partition of $X(\Gamma, \mathcal{G})$), then our collection of walls endows $X(\Gamma, \mathcal{G})$ with a structure of wallspace. The key observation is that the system of wallspace $\{ \mathcal{W}(C) \mid C \text{ clique} \}$ is coherent, meaning that, for every clique $C$ and $C'$ dual to the same hyperplane, the equality

$$t_{C \rightarrow C'} \mathcal{W}(C) = \mathcal{W}(C')$$

holds, where $t_{C \rightarrow C'}$ denotes the restriction to $C$ of the projection onto $C'$ (this map may be thought of as a “parallel transport” along the hyperplane dual to $C$ and $C'$). Indeed, because $C$ and $C'$ are dual to the same hyperplane of $X(\Gamma, \mathcal{G})$, there exist $g \in \Gamma \mathcal{G}$, $G \in \mathcal{G}$ and $h \in C_{\Gamma \mathcal{G}}(G)$ such that $C = gG$ and $C' = ghG$, so that

$$\mathcal{W}(C') = \mathcal{W}(ghG) = gh \mathcal{W}(G) = g \mathcal{W}(G)h = \mathcal{W}(C)h = t_{C \rightarrow C'} \mathcal{W}(C),$$
since the right-multiplication by \( h \) turns out to coincide with the map \( t_{gG \to ghG} \). As a consequence, the collections of walls \( \overline{W}(C) \) and \( \overline{W}(C') \) coincide if \( C \) and \( C' \) are two cliques dual to the same hyperplane \( J \). So it makes sense to define \( \mathcal{W}(J) \) as the collection \( \overline{W}(C) \) for any clique \( C \) dual to \( J \), and we finally endow \( X(\Gamma,G) \) with the collection of walls

\[
\mathcal{H}W = \bigcup_{J \text{ hyperplane}} \mathcal{W}(J).
\]

It can be proved that, if we write an element \( g \in \Gamma G \) as a word of minimal length \( g_1 \cdots g_n \), where \( g_i \) belongs to some \( G_i \in \mathcal{G} \) for every \( 1 \leq i \leq n \), then

\[
d_{\mathcal{H}W}(1, g) = \sum_{i=1}^{n} d_{W(G_i)}(1, g_i) = \sum_{i=1}^{n} d_{X_0(G_i)}(x_0(G_i), g_i \cdot x_0(G_i)),
\]

where \( d_{\mathcal{H}W}(\cdot, \cdot) \) denotes the number of walls in \( \mathcal{W} \) separating two vertices of \( X(\Gamma, G) \), and, for every \( G \in \mathcal{G} \), \( d_{W(G)}(\cdot, \cdot) \) the number of walls of \( \mathcal{W}(G) \) separating two points of \( G \) and \( d_{X_0(G)} \) the distance in the CAT(0) cube complex \( X_0(G) \). From this formula, it follows that only finitely many walls of \( \mathcal{H}W \) separate two given vertices of \( X(\Gamma,G) \), so that \( (X(\Gamma,G), \mathcal{H}W) \) defines a wallspace; and that the action of \( \Gamma G \) on the CAT(0) cube complex obtained by cubulating this wallspace is metrically proper. \( \square \)

In the previous argument, two points are fundamental:

- For every clique \( C \) of our quasi-median graph, the action \( \text{stab}(C) \leadsto C \) is free and transitive on the vertices. This allows us to identify a clique with its stabiliser in order to transfer some structure from \( \text{stab}(C) \) to \( C \) (in the previous proof, a collection of walls).
- There exists some compatibility between the action \( \Gamma G \leadsto X(\Gamma,G) \) and the maps \( t_{C \rightarrow C'} \), which implies that the collection of structures (in the previous proof, collections of walls) defined on each clique is coherent.

In \cite{11}, we introduced topical-transitive actions to recover these properties and to generalise the previous argument to other groups acting on quasi-median graphs.

**Definition 5.2.** — Let \( G \) be a group acting on a quasi-median graph \( X \). The action is topical if, for every hyperplane \( J \), every clique \( C \) dual to \( J \) and every element \( g \in \text{stab}(J) \), there exists some \( \rho_C(g) \in \text{stab}(C) \) such that \( g \) and \( \rho_C(g) \) induce the same permutation on the set of sectors delimited by \( J \). If moreover the action \( \text{stab}(C) \leadsto C \) is free and transitive on the vertices for every clique \( C \) which either is infinite or satisfies \( \text{stab}(C) \neq \text{fix}(C) \), the action \( G \leadsto X \) is topical-transitive.
Fix a group $G$ acting topically-transitively on some quasi-median graph $X$. For convenience, we suppose that the action $\text{stab}(C) \curvearrowright C$ is free and transitive on the vertices for every clique $C$ of $X$ (which happens, for instance, if all the cliques of $X$ are infinite). Fixing a collection of cliques $\mathcal{C}$ such that every orbit of hyperplane intersects $\mathcal{C}$ along exactly one clique ($\mathcal{C}$ can be thought of as a collection of cliques of reference), the key point is that, for every clique $C$ labelled by $Q \in \mathcal{C}$ (ie., some translate of $C$ is dual to the same hyperplane as $Q$), there exist a natural bijection $\phi_C : C \to Q$ and a natural isomorphism $\phi_C : \text{stab}(C) \to \text{stab}(Q)$, so that

- $\phi_C = \phi_{C'} \circ t_{C \to C'}$ for every clique $C$ and $C'$ dual to the same hyperplane;
- $\phi_{gC}(gx) = \varphi_C(s_C(g)) \cdot \phi_C(x)$ for every clique $C$, every vertex $x \in C$ and every element $g \in G$.

The map $s_C : G \to \text{stab}(C)$ is defined below, but the point to keep in mind is that $s_C(g) = g$ for every $g \in \text{stab}(C)$, so that $\phi_C$ turns out to be a $\varphi_C$-equivariant bijection.

Before describing the maps $\phi_C$ and $\varphi_C$, let us show how to create invariant and coherent systems of structures, as in the argument above. We illustrate the construction only for wallspaces, but the same idea can be applied to measured wallspaces, topologies, $\sigma$-algebras, and to collections of maps such as metrics, embeddings into Banach or Hilbert spaces, and so on.

**Proposition 5.3.** — Let $G$ be a group acting topically-transitively on some quasi-median graph $X$. Suppose that every vertex of $X$ belongs to finitely many cliques and that vertex-stabilisers are finite. If clique-stabilisers act metrically properly on CAT(0) cube complexes, then so does $G$.

**Sketch of proof.** Fix a collection of cliques $\mathcal{C}$ intersecting each orbit of hyperplanes along exactly one clique. For every $Q \in \mathcal{C}$, let $X(Q)$ be a CAT(0) cube complex on which $\text{stab}(Q)$ acts metrically properly. As above, use an orbit map to endow $\text{stab}(Q)$ with a $\text{stab}(Q)$-invariant structure of wallspace $W(Q)$. If $C$ is an arbitrary clique of $X$, labelled by $Q \in \mathcal{C}$ (ie., $C$ can be translated by an element of $G$ in the hyperplane dual to $Q$), set

$$W(C) = \phi_C^{-1}W(Q).$$

Notice that, for every clique $C$ and every element $g \in G$,

$$gW(C) = g\phi_C^{-1}W(Q) = \phi_{gC}^{-1}(\varphi_C(g) \cdot W(Q)) = \phi_{gC}^{-1}W(Q) = W(gC).$$
Therefore, our system of wallspaces is $G$-invariant. Moreover, if $C$ and $C'$ are two cliques dual to the same hyperplane, then
\[ W(C') = \phi^{-1}_{C'} W(Q) = t_{C \to C'} \circ \phi^{-1}_C W(Q) = t_{C \to C'} W(C). \]
So our system of wallspaces is also coherent. As a consequence, it makes sense to set, for every hyperplane $J$ of $X$,
\[ W(J) = \{ \{ \text{proj}^{-1}_C(D), \text{proj}^{-1}_C(D^c) \} \mid \{D, D^c\} \in W(C) \} \]
for some clique $C$ dual to $J$. We can show that
\[ \mathcal{H}W = \bigcup_{J \text{ hyperplane}} W(J) \]
endows $X$ with a $G$-invariant structure of wallspace, so that one finds an action of $G$ on the associated CAT(0) cubecomplex. Under the assumptions of our proposition, it can be proved that this action is metrically proper. □

Now, we focus on the maps $\phi_C$ and $\varphi_C$. Recall that the setting is the following: a group $G$ acts topically-transitively on a quasi-median graph $X$, we fix a collection of cliques $\mathcal{C}$ intersecting each orbit of hyperplanes along a single clique, and we suppose that every clique-stabiliser acts on its clique freely and transitively on the vertices. We also fix a vertex $x_0 \in X$, and, for every clique $C$, we denote by $x_0(C)$ the projection of $x_0$ onto $C$.

**Definition 5.4.** — Let $C$ be a clique and $g \in G$. Denote by $p_C(g)$ the unique element of $g \cdot \text{stab}(C)$ sending $x_0(C)$ to $x_0(gC)$ (such an element existing since $\text{stab}(C) \acts C$ is transitive on the vertices). Also, set $s_C(g) = p_C(g)^{-1}g$.

The picture to keep in mind is the following. We decompose $g$ as a prefix $p_C(g)$ and a suffix $s_C(g)$ such that $s_C(g) \in \text{stab}(C)$ “rotates” $C$ and such that $p_C(g)$ “translate” $C$ to $gC$.

**Definition 5.5.** — Let $C$ be a clique labelled by $Q \in \mathcal{C}$. Fix an element $g \in G$ satisfying $p_C(g) = g$ and such that $gC$ is dual to the same hyperplane as $Q$. We define
\[ \phi_C : \begin{cases} C & \to Q \\ x & \mapsto t_{gC \to Q}(gx) \end{cases} \quad \text{and} \quad \varphi_C : \begin{cases} \text{stab}(C) & \to \text{stab}(Q) \\ h & \mapsto \rho_Q(ghg^{-1}) \end{cases} \]

Roughly speaking, $\phi_C$ translates $C$ into the hyperplane dual to $Q$ (by left-multiplying by $g$) and next translates $gC$ along this hyperplane to $Q$ (thanks to the map $t_{gC \to Q}$); and $\varphi_C$ sends an element $h \in \text{stab}(C)$ to the unique element of $\text{stab}(Q)$ which induces the same permutation on the set of sectors delimited by $J$ as $ghg^{-1} \in \text{stab}(gC)$. It is worth noticing that these maps do not depend on our choice of $g$ [11, Claims 5.30 and 5.31].
5.1. Applications

The argument described in the proof of Proposition 5.3 can be applied to many different contexts. In [11], we state general combination theorems about:

- relative hyperbolicity [11, Theorem 5.17];
- metrically proper and geometric actions on CAT(0) cube complexes [11, Propositions 5.22 and 5.23];
- a-T-menability and a-$L^p$-menability [11, Propositions 5.25 and 5.26];
- (equivariant) $\ell^p$-compressions [11, Proposition 5.37].

As examples of concrete applications:

- we showed that a graph product (along a finite simplicial graph) of groups acting geometrically on CAT(0) cube complexes acts geometrically on a CAT(0) cube complex [11, Theorem 8.17];
- we determined precisely when a graph product is relatively hyperbolic [11, Theorem 8.35];
- we showed that acting metrically properly on some CAT(0) cube complex is stable under wreath products [11, Theorem 9.28] (see also [9, 13]);
- we computed equivariant $\ell^p$-compressions of some wreath products [11, Theorem 9.37].

A particular case of the last point is the following statement (in which $\alpha^*_p(\cdot)$ denotes the equivariant $\ell^p$-compression):

**Theorem 5.6.** — [11, Theorem 9.54] Let $H$ be a hyperbolic group acting geometrically on some CAT(0) cube complex. For every finitely generated group $G$ and every $p \geq 1$,

$$\alpha^*_p(G \wr H) \geq \min \left( \frac{1}{p}, \alpha^*_p(G) \right),$$

with equality if $H$ is non elementary and $p \in [1, 2]$.

Given a Lipschitz map $f : X \to Y$ between two metric spaces, the compression of $f$ is

$$\text{comp}(f) = \sup \{ \alpha \in [0, 1] \mid \exists C > 0, \forall x, y \in X, C \cdot d(x, y)^\alpha \leq d(f(x), f(y)) \}.$$ 

By extension, the compression of $X$ into $Y$ is

$$\alpha_Y(X) = \sup \{ \text{comp}(f) \mid f : X \to Y \text{ Lipschitz} \}.$$
So, roughly speaking, the compression quantifies the minimal distortion required to embed $X$ into $Y$. If $Y = L^p$, we denote by $\alpha_p(X)$ the corresponding compression, called the $\ell^p$-compression. There is an equivariant analogue of the $\ell^p$-compression. Namely, if $G$ is a group, then the equivariant $\ell^p$-compression is

$$\alpha^*_p(G) = \sup \{ \text{comp}(f) \mid G \actson L^p, f : G \rightarrow L^p \text{ Lipschitz } G\text{-equivariant} \}$$

where actions are always by isometries.

6. Topical-transitive actions on quasi-median graphs II

Given a group acting topically-transitively on a quasi-median graph, the strategy described in the previous section was to transfer structures from clique-stabilisers to cliques, to extend the collection of “local” structures to a “global” structure which is invariant under the group action, and finally to exploit this action to deduce information on the group. However, many interesting group properties cannot be expressed on the group itself. For instance, being CAT(0), i.e., acting geometrically on some CAT(0) space. In [11, Sections 6 and 7], we showed how to modify the first step of our strategy to avoid the difficulty. For instance, if we fix a group $G$ acting topically-transitively on some quasi-median graph $X$ and if we suppose that clique-stabilisers act on CAT(0) spaces, our strategy to construct a CAT(0) space on which $G$ acts is the following (once again, we suppose for simplicity that each clique-stabiliser acts freely and transitively on the vertices of its clique):

- Fix a collection of cliques $C$ intersecting each orbit of hyperplanes along a single clique, and, for every $C \in C$, fix a CAT(0) space $Y(C)$ on which $\text{stab}(C)$ acts. Without loss of generality, we may suppose that $Y(C)$ contains a point $y_0(C)$ whose stabiliser is trivial. As above, we also fix a basepoint $x_0 \in X$, and, for every clique $C$, we denote by $x_0(C)$ the projection of $x_0$ onto $C$. Using the map

$$\begin{cases} C & \rightarrow Y(C) \\ g \cdot x_0(C) & \mapsto g \cdot y_0(C), \end{cases}$$

we identify each clique $C \in C$ with a subspace of $Y(C)$.

- Next, we “add the missing vertices” to the clique $C$ to get a copy of $Y(C)$. This operation is called inflating the hyperplanes of $X$. The point is that we get a new quasi-median graph $Y$, containing $X$ as an isometrically embedded subgraph, such that each clique $C_+$,
which is the unique clique of $Y$ containing a given clique $C \in \mathcal{C}$, has its vertices in bijection with $Y(C)$. Moreover, if $\mathcal{C}_+$ denotes the collection of the $\mathcal{C}_+$’s, then the action $G \acts X$ extends to a $\mathcal{C}_+$-topical action $G \acts Y$. (However, the action is no longer topical-transitive since the actions $\text{stab}(C) \acts Y(C)$ are generally not transitive.)

• So far the situation is the following. Our group $G$ acts $\mathcal{C}_+$-topically on the quasi-median graph $Y$, and each clique $C \in \mathcal{C}_+$ can be naturally identified with the CAT(0) space $Y(C)$. Thus, now we can endow each clique $C \in \mathcal{C}_+$ with the CAT(0) metric of $Y(C)$. The next step would be to use the maps $\phi_C$ and $\varphi_C$ to construct a coherent and $G$-invariant system of CAT(0) metrics, but as the action is not topical-transitive these maps are no longer well-defined. However, it is possible to mimic the definitions of $\phi_C$ and $\varphi_C$ in more general contexts to construct maps with similar properties [11, Sections 5.1 and 5.2], so that we are able to extend our collection of CAT(0) metrics to a coherent and $G$-invariant system of CAT(0) metrics $\{ (C, \delta_C) \mid C \text{ clique} \}$. (The point is that our new maps $\phi_C$ and $\varphi_C$ are not canonical: they depend on choices of some elements of $G$. However, according to [11, Theorem 5.1], the system of metrics which is obtained does not depend on these choices.)

• Now, given our $G$-invariant and coherent system of metrics, we want to construct a global CAT(0) metric on $Y$ (or rather on the set of vertices of $Y$) which is invariant under the action of $G$. First, we endow each prism $P$ of $Y$, which is a product of cliques, with the $\ell^2$-product $\delta_P$ of the CAT(0) metrics defined on the corresponding cliques. Next, given two vertices $x, y \in Y$, a chain $\Sigma$ between $x$ and $y$ is a sequence of vertices

$$x_0 = x, x_1, \ldots, x_{n-1}, x_n = y$$

such that, for every $0 \leq i \leq n-1$, there exists a prism $P_i$ containing both $x_i$ and $x_{i+1}$. Its length is

$$\ell(\Sigma) = \sum_{i=1}^{n-1} \delta_{P_i}(x_i, x_{i+1}).$$

Finally, the global metric we define on (the vertices of) $Y$ is

$$\delta^2 : (x, y) \mapsto \inf \{ \ell(\Sigma) \mid \Sigma \text{ chain between } x \text{ and } y \}.$$ 

It can be proved that the space $(Y, \delta^2)$ is indeed CAT(0) [11, Proposition 3.11].

Of course, the previous strategy can be adapted to other kinds of spaces.
6.1. Applications

General criteria proved in [11] include:

- finding properly discontinuous actions on CAT(0) cube complexes [11, Proposition 7.4];
- finding virtually special and geometric actions on CAT(0) cube complexes [11, Proposition 7.5];
- finding geometric actions on CAT(0) spaces [11, Theorem 7.7].

As corollaries, one can prove that:

- graph products (along finite graphs) of CAT(0) groups are CAT(0) [11, Theorem 8.20];
- graph products (along finite graphs) of groups acting geometrically and virtually specially on CAT(0) cube complexes are virtually special [11, Theorem 8.17];
- acting properly on some CAT(0) cube complex is stable under wreath products [11, Corollary 9.29] (see also [9, 13]).

7. Towards a geometric study of automorphisms of graph products

Although there does not exist any general recipe to construct a geometric model of an automorphism group from a geometric model of the group itself, it turns out to be possible to study geometrically automorphisms of graph products from the associated quasi-median graphs. We would like to conclude this article by describing recent successes in this direction.

The key idea is to defined, purely algebraically, a graph on which the automorphism group of a given graph product acts by isometries, and next to state and prove a geometric interpretation of this graph in terms of the corresponding quasi-median graph. The objective being to exploit the powerful tools available to study quasi-median graphs in order to deduce some valuable information on this geometric model of the automorphism group. In [14], we proposed the following definition:

DEFINITION 7.1. — Let $\Gamma$ be a simplicial graph and $\mathcal{G}$ a collection of groups indexed by $V(\Gamma)$. The graph of products $P(\Gamma, \mathcal{G})$ is the graph

- whose vertices are the maximal product subgroups of $\Gamma \mathcal{G}$, ie., the subgroups of $\Gamma \mathcal{G}$ which are maximal with respect to the inclusion among all the subgroups which splits non-trivially as direct products;
• and whose edges link two subgroups whenever their intersection is non-trivial.

The automorphism group $\text{Aut}(\Gamma \mathcal{G})$ acts naturally on the graph of products via

$$\begin{align*}
\text{Aut}(\Gamma \mathcal{G}) & \rightarrow \text{Isom}(P(\Gamma, \mathcal{G})) \\
\varphi & \mapsto (H \mapsto \varphi(H))
\end{align*}$$

The geometric counterpart of the graph of products is:

**Definition 7.2.** — Let $\Gamma$ be a simplicial graph and $\mathcal{G}$ a collection of groups indexed by $V(\Gamma)$. The geometric product graph $GP(\Gamma, \mathcal{G})$ is the graph

• whose vertices are the maximal join subgraphs, i.e., the subgraphs $g(\Lambda) \subset X(\Gamma, \mathcal{G})$ where $g \in \Gamma \mathcal{G}$ is an element and $\Lambda \subset \Gamma$ is a maximal join (with respect to the inclusion);

• whose edges link two subgraphs whenever the projection of one onto the other is not reduced to a single vertex, or equivalently, if there exists a hyperplane intersecting them.

The connection between these two graphs is made by [14, Proposition 2.30], namely:

**Proposition 7.3.** — Let $\Gamma$ be a simplicial graph and $\mathcal{G}$ a collection of groups indexed by $V(\Gamma)$. The map

$$\begin{align*}
GP(\Gamma, \mathcal{G})^{(0)} & \rightarrow P(\Gamma, \mathcal{G})^{(0)} \\
S & \mapsto \text{stab}(S)
\end{align*}$$

induces a graph isomorphism $GP(\Gamma, \mathcal{G}) \rightarrow P(\Gamma, \mathcal{G})$.

By exploiting the quasi-median geometry of $X(\Gamma, \mathcal{G})$ and the previous geometric interpretation of the graph of products $P(\Gamma, \mathcal{G})$, we were able to prove the following statement in [14, Theorem 2.38]:

**Theorem 7.4.** — Let $\Gamma$ be a finite and connected simplicial graph, and let $\mathcal{G}$ be a collection of groups indexed by $V(\Gamma)$. Then $P(\Gamma, \mathcal{G})$ is a graph quasi-isometric to a tree on which $\text{Aut}(\Gamma \mathcal{G})$ acts cocompactly. Moreover, $P(\Gamma, \mathcal{G})$ is unbounded if and only if $\Gamma$ is not a join.

Unfortunately, the graph of products remains difficult to work, additional works will be needed to understand the dynamics of the action $\text{Aut}(\Gamma \mathcal{G}) \curvearrowright P(\Gamma, \mathcal{G})$ in order to deduce valuable information on $\text{Aut}(\Gamma \mathcal{G})$ in full generality. Nevertheless, it is possible to use simplified geometric models of the automorphism group in some specific cases. The first success in this direction is the following statement proved in [15]:
Theorem 7.5. — Let $\Gamma$ be a simplicial graph and $\mathcal{G}$ a collection of groups indexed by $V(\Gamma)$. The group of conjugating automorphism of $\Gamma \mathcal{G}$ is generated by local automorphisms and partial conjugations.

An automorphism of a graph product $\Gamma \mathcal{G}$ is conjugating if it sends a vertex-group to a conjugate of a vertex-group (not necessarily the same). We refer to [15] for precise definitions of local automorphisms and partial conjugations. The point is that the theorem above provides a natural and simple generating set of a specific subgroup of the automorphism group. Although it might seem to be technical, this statement has several interesting consequences. For instance, it follows that the subgroup generated by partial conjugations has finite index in the entire automorphism group when vertex-groups are all finite. Also, we proved a rigidity about graph products defined over molecular graphs. We refer to [15] for more details.

Another success of this approach was achieved in [14]. There, the following statement is proved:

Theorem 7.6. — Let $\Gamma$ be a finite, connected and square-free simplicial graph. The automorphism group $\operatorname{Aut}(A_\Gamma)$ of the right-angled Artin group $A_\Gamma$ is acylindrically hyperbolic if and only if $\Gamma$ does not decompose as a join and contains at least two vertices.
